(54) Title: **PROCESS FOR REMOVING SULFUR FROM A HYDROCARBON FEED**

(57) Abstract: A method is provided for removing sulfur from an effluent produced by hydrotreating a hydrocarbon feed, said effluent having a heavy fraction containing polyaromatic sulfur compounds and a lighter fraction, said method comprising contacting the effluent with a noble metal containing hydrodearomatization catalyst on a support under super-atmospheric hydrogen pressure and reaction conditions sufficient to hydrogenate at least one ring of said polyaromatic sulfur compounds and thereby produce a product with a reduced sulfur content.

## PROCESS FOR REMOVING SULFUR FROM A HYDROCARBON FEED

Heavy petroleum fractions, such as vacuum gas oil or residues may be catalytically cracked to lighter and more valuable products. The product of catalytic cracking is conventionally recovered and the products fractionated into various fractions such as light gases; naphtha, including light and heavy gasoline; distillate fractions, such as heating oil and diesel fuel; lube fractions; and heavier fractions.

Generally, sulfur occurs in petroleum and petroleum products as hydrogen sulfide, organic sulfides, organic disulfides, mercaptans, also known as thiols, and aromatic ring compounds such as thiophene, benzothiophene (BT), dibenzothiophene (DBT) and their alkylated homologs. The sulfur in aromatic sulfur-containing ring compounds will be herein referred to as "thiophenic sulfur".

Where a petroleum fraction is being catalytically cracked and contains sulfur, the products of catalytic cracking usually contain sulfur impurities which normally require removal, usually by hydrotreating, in order to comply with the relevant product specifications. Such hydrotreating can be done either before or after catalytic cracking.

Conventionally, feeds with substantial amounts of sulfur, for example, those with more than 500 ppm sulfur, are hydrotreated with conventional hydrotreating catalysts under conventional conditions, thereby changing the form of most of the sulfur in the feed to hydrogen sulfide. The hydrogen sulfide is then removed by amine absorption, stripping or related techniques. Unfortunately, these techniques often leave some traces of sulfur in the feed, including thiophenic sulfur, which are the most difficult types to convert.

The ease of sulfur removal from petroleum and its products is dependent upon the type of sulfur-containing compound. Mercaptans are relatively easy to remove, whereas aromatic compounds such as thiophenes are more difficult to remove. Of the

thiophenic sulfur compounds, the alkyl substituted dibenzothiophenes are particularly resistant to hydrodesulfurization.

Hydrotreating any of the sulfur containing fractions which boil in the distillate boiling range, such as diesel fuel, causes a reduction in the aromatic content thereof, and therefore an increase in the cetane number of diesel fuel. While hydrotreating reacts hydrogen with the sulfur containing molecules in order to convert the sulfur and remove such as hydrogen sulfide, as with any operation which reacts hydrogen with a petroleum fraction, the hydrogen does not only react with the sulfur as desired. Other contaminant molecules contain nitrogen, and these components undergo hydrodenitrogenation in a manner analogous to hydrodesulfurization. Unfortunately, some of the hydrogen may also cause hydrocracking as well as aromatic saturation, especially during more severe operating conditions of increased temperature and/or pressure. Typically, as the degree of desulfurization increases, the cetane number of the diesel fuel increases; however this increase is generally slight, usually from 1-3 numbers.

The current specification for diesel fuel permits a maximum sulfur content of 0.05 wt%. However, the EPA is expected to propose new diesel fuel specifications that will become effective in 2004. The new specification is likely to require further reduction of sulfur content in diesel fuels to below 50 ppmw. Recently, the European Union published new diesel specifications, which limit the sulfur content in diesel fuels to a maximum of 350 ppmw after the year 2000, and to 50 ppmw maximum after the year 2004. In addition, the specifications may require an increase in the cetane value of diesel fuels to 58 in the year 2005, and a reduction in the polyaromatics content.

Hydrotreating can be effective in reducing the level of sulfur to moderate levels, e.g. 500ppm, without a severe degradation of the desired product. However, to achieve the levels of desulfurization that will be required by the new regulations, almost all sulfur compounds will need to be removed, even those that are difficult to remove such as DBTs. These refractory sulfur compounds can be removed by

distillation, but with substantial economic penalty, i.e., downgrading a portion of automotive diesel oil to heavy fuel oil.

Thus, there remains a need for a method of removing sulfur from a hydrocarbon feed under moderate process conditions.

The present invention is a method for removing sulfur from an effluent produced by hydrotreating a hydrocarbon feed. A process is provided in which the sulfur remaining in the effluent from the hydrotreating process is removed by contacting the effluent with a noble metal containing hydrodearomatization (HAD) catalyst on a support under reaction conditions sufficient to hydrogenate at least one ring within the polyaromatic sulfur compounds. The hydrogenated DBTs are then desulfurized at a rate that is 10-50 times faster than the original aromatic parent molecules over the same noble metal catalyst or any other conventional hydrotreating catalyst.

In a preferred embodiment, the lighter fraction of effluent from the hydrotreating process is first separated from the heavier fraction of effluent before the heavier fraction is contacted with the hydrodearomatization catalyst. In another preferred embodiment, the  $H_2S$  and  $NH_3$  produced by the hydrotreating step are removed before the effluent is contacted with said hydrodearomatization catalyst. In a further preferred embodiment, the  $H_2S$  and  $NH_3$  are removed from the effluent, along with the lighter fraction, before the heavier fraction is contacted with the hydrodearomatization catalyst.

The support for the hydrodearomatization catalyst can be selected from the group consisting of gamma- $Al_2O_3$ , zeolite beta, USY, ZSM-12, mordent,  $TiO_2$ , ZSM-48, MCM-41,  $SiO_2$ ,  $ZrO_2$ ,  $\eta-Al_2O_3$ ,  $\theta-Al_2O_3$ , SAPOs, MEAPOs,  $AlPO_4$ s, or a combination thereof. The noble metal catalyst of the dearomatization catalyst can be selected from the group consisting of platinum, palladium, ruthenium, rhodium, iridium, osmium, rhenium, or a combination thereof. Platinum is preferred.

In another embodiment of the invention, the method further includes contacting at least the heavy fraction of the effluent from the hydrotreating process with a hydrodesulfurization (HDS) catalyst. It is preferred that the hydrodesulfurization

5 catalyst contains a base metal. Typical HDS catalysts include but are not limited to, CoMo/Al<sub>2</sub>O<sub>3</sub>, NiMo/Al<sub>2</sub>O<sub>3</sub>, NiW/Al<sub>2</sub>O<sub>3</sub>, and NiCoMo/Al<sub>2</sub>O<sub>3</sub>.

The effluent from the hydrotreating step is contacted with the hydrodearomatization catalyst and the hydrodesulfurization, which are arranged within  
10 a reaction vessel. This arrangement within the reaction vessel can consist of various schematics. One schematic is with the hydrodearomatization catalyst and the hydrodesulfurization catalyst combined in two separate layers, or in multiple alternating layers. Another is with the hydrodearomatization catalyst and the hydrodesulfurization catalyst being separate extrudates, which are mixed. Another  
15 schematic is with the hydrodearomatization catalyst and the hydrodesulfurization catalyst and the metal of the hydrodesulfurization catalyst are co-incorporated. The schematic can also be any combination thereof.

Process conditions will vary based upon the properties of the effluent feed.  
20 However, the preferred operating conditions generally include a temperature of 550 - 800°F, a pressure of 200 - 1100 psig, an LHSV of 0.5 - 10 hr<sup>-1</sup>, and a H<sub>2</sub> recycle rate of 300 - 2500 SCFB.

Thus, the present invention provides a method of removing sulfur from a  
25 hydrocarbon feed at a lower temperature and pressure, and with lower capital investment.

Figure 1 is a graph demonstrating the relative concentration of sulfur compounds plotted as a function of boiling range for LGO at different  
30 hydrodesulfurization conversions.

Figure 2 is a graph demonstrating the relative percentage of sulfur compounds plotted as a function of molecular weight for different hydrodesulfurization conversions.

5 Figure 3 is a schematic of a process configuration, which includes interstage separation of  $H_2S$  and  $NH_3$  from the effluent after hydrotreating.

Figure 4 is a schematic of a process configuration of the invention, which includes interstage distillation.

10 Figure 5 is a schematic of a process configuration of the invention, which includes interstage stripping and both a hydrodearomatization catalyst and a hydrodesulfurization catalyst in the second reactor.

15 Figure 6 is a schematic of a process configuration of the invention, which includes interstage distillation and both a hydrodearomatization catalyst and a hydrodesulfurization catalyst in the second reactor.

20 Figure 7 is a schematic of a process configuration used in the Example, which includes a platinum-containing hydrodearomatization catalyst.

In accordance with the present invention, a process is provided for the removal of sulfur compounds from a hydrocarbon feed. Unlike conventional desulfurization methods which rely on extreme process conditions or unique combinations of  
25 feedstock, catalyst volume, and pressure; the process of the invention relies upon the ability to process the petroleum at an increased reactor volume through the selective hydrogenation and removal of polyaromatic sulfur compounds which impede the desulfurization process.

30 The feedstock can generally be described as high boiling point feeds of petroleum origin. In general, the feeds will have a boiling point range of about 350°F to about 750°F (about 175°C to about 400°C), preferably about 400°F to about 700°F

(about 205°C to about 370°C). Generally, the preferred feedstocks are: (a) non-thermocracked streams, such as gas oils distilled from various petroleum sources, (b) catalytically cracked stocks, including light cycle oil (LCO) and heavy cycle oil (HCO), clarified slurry oil (CSO), and (c) thermally cracked stocks such as coker gas oils,  
5 visbreaker partial hydrotreatment.

Cycle oils from catalytic cracking processes typically have a boiling range of about 400°F to 750°F (about 205°C to 400°C), although light cycle oils may have a lower end point, e.g. 600°F or 650°F (about 315°C or 345°C). Because of the high  
10 content of aromatics and poisons such as nitrogen and sulfur found in such cycle oils, they require more severe hydrotreating conditions, which can cause a loss of distillate product. Lighter feeds may also be used, e.g. about 250°F to about 400°F (about 120°C to about 205°C). However, the use of lighter feeds can result in the production of lighter distillate products, such as kerosene.

15 In the first step of the process, the feed is hydrotreated under conventional methods in a to convert nitrogen and sulfur containing compounds to gaseous ammonia and hydrogen sulfide. At this stage, hydrocracking is minimized, but partial hydrogenation of polycyclic aromatics proceeds, together with a limited degree of  
20 conversion to lower boiling (343°C, 650°F) products. The catalyst used in this stage may be a conventional hydrotreating catalyst. Catalysts of this type are relatively immune to poisoning by the nitrogenous and sulfurous impurities in the feedstock and generally comprise a non-noble metal component supported on an amorphous, porous carrier such as silica, alumina, titania, silica-alumina or silica-magnesia.  
25 Because extensive cracking is not desired in this stage of the process, the acidic functionality of the carrier should be relatively low.

The metal component of the hydrotreating catalyst may be a single metal from Groups VIA and VIIIA of the Periodic Table such as nickel, cobalt, chromium,  
30 vanadium, molybdenum, tungsten, or a combination of metals such as nickel-molybdenum, cobalt-nickel-molybdenum, cobalt-molybdenum, nickel-tungsten or nickel-tungsten-titanium. Generally, the metal component will be selected for good

hydrogen transfer activity. The catalyst as a whole will have good hydrogen transfer and minimal cracking characteristics. The catalyst should be pre-sulfided in the normal way in order to convert the metal component (usually impregnated into the carrier and converted to oxide) to the corresponding sulfide, and oxysulfide.

5

After desulfurization in the hydrotreating step and removal of  $H_2S$  and  $NH_3$ , the resulting effluent contains approximately 500 ppm sulfur or less. Essentially all of the remaining sulfur containing compounds remaining in the effluent are sterically hindered dibenzothiophene (DBT) and its alkyl homologs, which are difficult to desulfurize. Table 1 demonstrates the relative reactivity of the various sulfur containing compounds that may be contained in the hydrocarbon effluent or feed.

10

**TABLE 1**  
**Relative Rate of Hydrodesulfurization**

Reactant	Structure	First Order Relative Rate Constant
Thiokol	R-SH	5000
Disulfides	RSSR	5000
Sulfides	RSR	5000
Thiophene		5000
Benzothiophene		2900
Dibenzothiophene (DBT)		220
4,6-Dimethyl dibenzothiophene		22
4,6-Tribenzothiophene		1100

- (a) R refers to any hydrocarbon Group attached to the sulfur atom.
- (b) B.C. Gates, J.R. Katzer, and G.C.A. Schuit, "Chemistry of Catalytic Processes," McGraw-Hill (1979) and H. Topsøe, B. S. Clausen, and F.E. Massoth, "Hydrotreating Catalysis: Science and Technology," Springer (1966).

As shown in Table 1, the rate of reactivity of hydrodesulfurization is low for DBT compounds, particularly 4,6-dimethyl dibenzothiophene.

The boiling range of substituted and non-substituted DBT is 530 - 750°F. This boiling range is shown in Fig. 1. As the percent desulfurization increases, the relative percentage of DBTs increase. Fig. 2 displays the same trend for a heavier VGO feed. The higher molecular species are desulfurized more readily than the DBTs, which indicates the difficulty of desulfurizing these sterically hindered species.

To increase the rate of desulfurization of a hydrocarbon source containing the sterically hindered species, the focus must be shifted from the conventional process of direct desulfurization. The process of the invention increases the rate of desulfurization by increasing the reactivity of the polyaromatic sulfur compounds, including DBTs, remaining in the effluent after the hydrotreating step. The rate of reactivity of these compounds is increased by hydrogenating one or more of the aromatic rings, thereby shifting the reactivity upward from that of the polyaromatic sulfur compounds to that of sulfides.

Since the sulfur containing compounds remaining in the effluent after the hydrotreating mainly consists of DBTs, and DBTs have the slowest desulfurization rate, DBTs are the primary concern. The typical desulfurization reaction of 4,6-dimethyl DBT is:

(I)

At a pressure less than 800 psig with a conventional base metal catalyst, this reaction is extremely slow. At higher pressures, e.g. 1200 – 2000 psig, one of the aromatic rings can be hydrogenated in the presence of a base metal catalyst as follows:

(II)

However, it is undesirable to operate at such severe pressure conditions because of the capital costs associated with the equipment. The process of the invention allows for the desired reactions to occur at much lower pressures. A process of the invention, shown in equation 3, and a conventional route, shown in equation 4, are as follows:

(III)

(IV)

All of the rate constants of the process of the invention are approximately equal and about 250 times larger than the constant rate of the base catalyst in a conventional hydrotreating reactor.

Thus, after the hydrocarbon feed has been hydrotreated, the effluent includes a heavy fraction containing polyaromatic sulfur compounds and a lighter fraction.

The effluent is contacted with a noble metal containing hydrodearomatization catalyst on a support under super-atmospheric hydrogen pressure and reaction

conditions sufficient to hydrogenate at least one ring of the polyaromatic sulfur compounds, and thereby produce a product with a reduced sulfur content.

It is preferred that the hydrotreatment process be performed in a first reaction vessel and the effluent from the hydrotreatment step can be contacted with the hydrodearomatization catalyst in a second reaction vessel. However, with an appropriate hydrocarbon feed and under appropriate process conditions, it is possible to have a reactor scheme where the hydrotreating catalyst and hydrodearomatization catalyst are contained within the same reactor.

In the hydrotreating stage, the nitrogen and sulfur impurities are converted to ammonia and hydrogen sulfide. At the same time, the polycyclic aromatics are partially hydrogenated to form naphthenes and hydroaromatics. It is known that ammonia and hydrogen sulfide can poison a noble metal catalyst.

Therefore, in a preferred embodiment, the ammonia and hydrogen sulfide are removed from the effluent by a conventional interstage separation process, such as interstage stripping or distillation, before the effluent proceeds to the noble metal containing hydrodearomatization catalyst. (See fig. 3.) The interstage separation removes  $H_2S$ ,  $NH_3$  and light gases, e.g.,  $C_1$ - $C_4$  hydrocarbons, from the effluent before the effluent proceeds to the hydrodearomatization catalyst.

In a separate preferred method, the  $H_2S$  and  $NH_3$  are separated along with a light fraction of the effluent. This separation can be performed during interstage distillation. This separation allows the high boiling point product of approximately 530 - 750°F to be separately contacted with the hydrodearomatization catalyst. A schematic is shown in Figure 4. The light fraction, i.e. effluent boiling from approximately 330 - 550°F, which is virtually free of sulfur, can then be recombined with the processed higher boiling range product yielding a mixture containing 50 ppm sulfur or less. Because the lighter fraction of effluent is removed, the addition of a distillation column enables a much smaller second reactor to be used with more specific operating parameters when the heavier effluent is contacted with the hydrodearomatization

catalyst. In the case with no interstage stripping, hydrogen quenching may be carried out in order to control the effluent temperature and to control the catalyst temperature in the hydrodearomatization stage.

5       The use of a noble metal hydrodearomatization catalyst allows for very controllable hydrogenation of aromatics at lower temperature or pressure conditions. Due to easier, and hence faster, desulfurization of the partially hydrogenated polyaromatic sulfur compounds, including DBTs, the equilibrium of the hydrogenation reaction is pushed toward completion even at low pressure, where equilibrium for  
10 hydrogenation is not favored. This allows for virtually complete desulfurization, if required.

Noble metal catalysts can accomplish efficient hydrogenation. The reaction rates for hydrogenation to hydrodesulfurization is high for noble metal catalysts. The  
15 noble metal catalyst can be selected from the group consisting of platinum, palladium, ruthenium, rhodium, iridium, osmium, rhenium, platinum/palladium, or other combinations thereof. Platinum is preferred. Platinum has a relative rate constant four times greater than that of the other noble metal catalysts.

20       The noble metal catalyst can be supported by any known support material. Preferably, the support material is selected from the group consisting of gamma- $\text{Al}_2\text{O}_3$ , zeolite beta, USY, ZSM-12, mordenite,  $\text{TiO}_2$ , ZSM-48, MCM-41,  $\text{SiO}_2$ ,  $\text{ZrO}_2$ ,  $\eta - \text{Al}_2\text{O}_3$ ,  $\theta - \text{Al}_2\text{O}_3$ , SAPOs, MEAPOs,  $\text{AlPO}_4$ s. Zeolite catalysts are a potentially superior support because they generate a more sulfur tolerant hydrogenation function than their  
25 alumina-based counter parts. However, sensitivity to nitrogen poisoning can be higher with zeolites so support selection is strongly dependent on feed composition. Two frequently employed supports are alumina (especially the gamma phase) and amorphous  $\text{SiO}_2/\text{Al}_2\text{O}_3$ .

30       Process conditions during contact with the hydrodearomatization catalyst will vary based upon the properties of the effluent feed. However, the preferred operating

conditions generally include a temperature of 550 - 800°F, a pressure of 200 – 1100 psig, an LHSV of 0.5 – 10hr<sup>-1</sup>, and a H<sub>2</sub> recycle rate of 300 – 2500 SCFB.

One potential limitation to using a zeolite based metal catalyst occurs with the  
5 operating conditions. With this type of catalyst, the temperature should remain below 600°F. Above this point, hydrocracking can occur; below this point generally hydrogenation occurs. The operating temperature can be extended above 600°F if the zeolite acidity has been substantially reduced by conventional means, e.g. direct  
10 synthesis to very high framework SiO<sub>2</sub>/Al<sub>2</sub>O<sub>3</sub> ratio, hydrothermal dealumination, silicon enrichment via ammonium hexafluorosilicate, back titrations with alkali metal cations, etc.

In a preferred embodiment, the method of the invention further includes  
contacting at least the heavy fraction of effluent with hydrodesulfurization catalyst. The  
15 additional bed of hydrodesulfurization catalyst can be an extra assurance that the partially saturated polyaromatic sulfur compounds will be desulfurized. The hydrodesulfurization catalyst can be conventional and will usually contain a metal, preferably a base metal.

20 The hydrodesulfurization catalyst can be included in the method of the invention in various schematics. The hydrodearomatization catalyst and the hydrodesulfurization catalyst will usually be contained together in a second reactor separate from the reactor containing the hydrotreating catalyst.

25 In one schematic, the hydrodearomatization catalyst and hydrodesulfurization catalyst can be combined in two separate layers, or in multiple alternating layers. In a preferred embodiment, the effluent from the hydrotreating step can be first contacted by the hydrodearomatization catalyst, followed by the hydrodesulfurization catalyst. Figure 5 is a schematic showing the use of both catalysts in a second reactor after  
30 interstage stripping. Figure 6 is a schematic showing the use of both catalysts after interstage distillation.

The hydrodearomatization catalyst and hydrodesulfurization catalyst can be two separate extrudes which are mixed. It is preferred that the two extrudates be of similar cross-sectional size and length. Also, the hydrodearomatization catalyst and the hydrodesulfurization catalyst can be a single extrudate in which the noble metal of the hydrodearomatization catalyst and metal(s) of the hydrodesulfurization catalyst are co-incorporated. Combinations of the schematics described are also possible.

The method of the invention was tested on two different blends of crude oil feedstocks, and their blends with LCO, CGO and VBGO. The sulfur content, the nitrogen content and the aromatic percentage are listed in Table 2 for each blend and for the cycle oil or gas oil components of each blend. Blend 1 had a sulfur content of 13000 ppm. Blend 2 had a sulfur content of 1584 ppm.

A high activity Nickel-Moly hydrotreating catalyst was employed as the first catalyst. Commercially available catalysts and suitable for this service are catalysts known as KF-840, KF-841, KF-843, KF-846 and KF-848 available from Akzo-Nobel; DN-110, DN-120, DN-140, DN-180, DN-190, DN-190+, DN-200, C-411 and C-424 available from Criterion Catalysts; HC-H, HC-K, HC-P and HC-R available from UOP; HR-346, HR-348, HR-360, HPC-50, HPC-60, HPC-312, HPC-416, HPC-40B available from Acreon Catalysts or alternately from Procatalyse or Englehard; TK-451, TK-525, TK-551, and TK-555 available from Haldor Topsoe; CR-565, CR-535, CR-599, CR-526, and CR-522 available from Crosfield Catalysts or catalysts of similar performance from other suppliers.

The process conditions employed were:

Liquid Hourly Space Velocity, Vol./hr. Vol.	1.7
Hydrogen Circulation, SCF/B	1000 - 2000
Reactor Inlet Hydrogen Partial Pressure, psia	800
Weighted Average Reactor Bed Temperature	600 - 650

The sulfur contents are listed in Table 2 for each blend and for the cycle and gas oil components of each blend after the hydrotreating (HDT) step. Through hydrotreating the sulfur content of Blend 1 was reduced from 13000 to 299. The sulfur content of Blend 2 was reduced from 1584 to 144. The sulfur content within the blends containing LCO, CGO, and VBGO were also significantly reduced. The remaining sulfur contains mainly polyaromatic sulfur compounds, which are difficult to remove.

**Table 2**

PtCat	19	32	32	23	21	18	23	26	23	18

5 The effluent from the hydrotreating step was then contacted with a hydrodearomatization catalyst. A schematic of the method is provided in Fig. 7. The hydrodearomatization catalyst consisted of platinum supported large pore zeolite.

10 The process conditions included a temperature of approximately 700°F and a pressure of 400 psig. Process conditions employed for the hydrodearomatization reaction system were:

	Liquid hourly space Velocity, vol./hr. Vol	1.5
	Hydrogen Circulation, SCF/	700 – 1500
15	Reactor Inlet hydrogen Partial Pressure, psia	650
	Weighted Average Reactor Bed Temperature, °F	660 – 720

20 Table 2 shows the severe desulfurization achieved by the method of the invention. Table 3 shows similar severe hydrodenitrogenation achieved in this catalyst system. After the effluent from the hydrotreating step is contacted by the hydrodearomatization catalyst, the sulfur content is reduced in Blend 1 from 299 ppm to 31 ppm. The sulfur content in Blend 2 was reduced from 144 ppm in the effluent of the hydrotreating step to 9 ppm. This shows the extraordinary ability for the method of the invention to desulfurize the effluent produced by hydrotreating a hydrocarbon  
25 feedstock, even though the sulfur containing compounds that are normally difficult to

remove. Table 4 shows total aromatics conversion/saturation, which is not necessarily required or necessary for HDS or HDS in this case. Overall aromatics saturation may be low in some cases because of unfavorable equilibrium for saturation reactions. Nonetheless, saturation of sulfur containing and nitrogen  
5 containing rings proceeds rapidly.

Thus, while there have been described what are presently believed to be the preferred embodiments of the invention, those skilled in the art will realize that changes and modifications may be made thereto without departing from the spirit of  
10 the invention, and it is intended to claim all such changes and modifications as fall within the scope of the invention.

Claims

1. A method of removing sulfur from an effluent produced by hydrotreating a hydrocarbon feed, said effluent having a heavy fraction containing polyaromatic sulfur compounds and a lighter fraction, said method comprising contacting the effluent with a noble metal containing hydrodearomatization catalyst on a support under super-atmospheric hydrogen pressure and reaction conditions sufficient to hydrogenate at least one ring of said polyaromatic sulfur compounds and thereby produce a product with a reduced sulfur content.

2. A method as described in Claim 1 wherein said lighter fraction of effluent is separated from said heavier fraction of effluent, and said heavier fraction is contacted with said hydrodearomatization catalyst.

3. A method as described in Claim 1 wherein  $H_2S$  and  $NH_3$  produced by the hydrotreating step are removed before the effluent is contacted with said hydrodearomatization catalyst.

4. A method as described in Claim 3 wherein the  $H_2S$  and  $NH_3$  are removed from the effluent along with the lighter fraction, before the heavier fraction is contacted with said hydrodearomatization catalyst.

5. A method as described in Claim 1 wherein said support is selected from the group consisting of gamma- $Al_2O_3$ , zeolite beta, USY, ZSM-12, mordenite,  $TiO_2$ , ZSM-48, MCM-41,  $SiO_2$ ,  $ZrO_2$ ,  $\eta-Al_2O_3$ ,  $\delta-Al_2O_3$ , SAPOs, MEAPOs,  $AlPO_4$ s, or a combination thereof.

6. A method as described in Claim 1 wherein said noble metal catalyst is selected from the group consisting of platinum, palladium, ruthenium, rhodium, iridium, osmium, rhenium, platinum/palladium or other combinations thereof.

7. A method as described in Claim 1 further comprising contacting at least said heavy fraction of effluent with a metal containing hydrodesulfurization catalyst.

8. A method as described in Claim 7 wherein the metal is a base metal.

9. A method as described in Claim 7 wherein the hydrodearomatization catalyst and hydrodesulfurization catalysts are arranged within a reaction vessel in a schematic selected from the group consisting of:

(a) said hydrodearomatization catalyst and said hydrodesulfurization catalyst combined in two separate layers or in multiple alternating layers,

(b) said hydrodearomatization catalyst and said hydrodesulfurization catalyst are separate extrudates which are mixed, and

(c) said hydrodearomatization catalyst and said hydrodesulfurization catalyst are a single extrudate in which the noble metal of the hydrodearomatization catalyst and the metal of the hydrodesulfurization catalyst are co-incorporated,

or a combination thereof.

10. A method as described in Claim 1 wherein the reaction conditions include a temperature of 550 - 800°F, a pressure of 200 - 1100 psig, and LHSV of 0.5 - 10 hr<sup>-1</sup>, and a H<sub>2</sub> recycle rate of 300 - 2500 SCFB.

1/7

FIG. 1

- Feed 1.25 wt% sulfur
- △— 72% HDS to 0.35 wt% sulfur
- 85% HDS to 0.19 wt% sulfur
- ◇— 95% HDS to 0.07 wt% sulfur

2/7

FIG. 7

# INTERNATIONAL SEARCH REPORT

International application No.

PCT/US00/33406

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : C10G 45/02, 45/10, 65/04

US CL : 208/89, 210, 211, 212, 217

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 208/89, 210, 211, 212, 217

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	US 4,973,396 A (MARKLEY) 27 November 1990 (27.11.1990), column 2, lines 66-68; column 3, lines 1-18 and 39-68; column 4, lines 1-6 and 30-68; and column 5, lines 6-20.	1-10
Y	US 5,925,239 A (KLEIN et al) 20 July 1999 (20.07.1999), column 2, lines 64-68; column 3, lines 1-39; column 4, lines 1-30; and column 9, lines 15-67.	1-10

☐ Further documents are listed in the continuation of Box C.

☐ See patent family annex.

\* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier application or patent published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T"

later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X"

document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y"

document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&"

document member of the same patent family

Date of the actual completion of the international search

02 January 2001 (02.01.2001)

Date of mailing of the international search report

01 MAR 2001
